# Definition of homotopy levels

isofhlevel: Nat 
$$\rightarrow$$
 Type  $\rightarrow$  Prop  
isofhlevel(o)(X) := isContr(X)  
isofhlevel(S(n))(X) :=  $\prod_{x,x':X}$  isofhlevel(n,x  $\leadsto$  x')

#### Definition

Set 
$$:= \sum_{X:\mathsf{Type}} \mathsf{isofhlevel(2)}(X)$$

- Any two parallel paths in a set are homotopic.
- Any closed path (loop) on x is homotopic to the constant path refl(x).

# Decidable equality

### Definition

A type *X* is **decidable** if there is a term of type

$$X + \neg X$$

### **Definition**

A type *X* has **decidable path-equality** if we can write a term of type

$$\prod_{x,x':A} (x \leadsto x') + \neg (x \leadsto x')$$

(that is, if all its paths types are decidable)

# Hedberg's theorem

#### Theorem

*If a type X has decidable equality, then it is a set.* 

In the problem session, we will show that Bool and Nat are sets.

# Closure properties

- $\sum_{x:A} B(x)$  is a set if A and all B(x) are
- $A \times B$  is a set if A and B are
- $\prod_{x:A} B(x)$  is a set if all B(x) are
- $A \rightarrow B$  is a set if B is
- *A* is a set if it is a proposition

### Exercise

### Do you know

- a type that is a set?
- a type for which you don't know (yet) whether it is a set?
- a type for which you know it is not a set?

### Another set

#### Theorem

The type

Prop := 
$$\sum_{X:\text{Type}} \text{isaprop}(X)$$

is a set.

The proof relies on the univalence axiom for the universe Type.

#### Exercise

How would you generalize the above statement to any h-level? How would you attempt proving it?

# Are all types sets?

## Is there a type that is not a set?

### It depends:

- In Martin-Löf type theory some types can not be shown to be sets.
- In univalent type theory some types can be shown not to be sets.

## Types that are **not** sets

Suppose that Type is a univalent universe containing the type Bool.

#### Exercise

Show that Type not a set.

Which property of Bool does the proof of the above result exploit?

#### Exercise

Show that

$$\mathsf{Set} \equiv \sum_{X:\mathsf{Type}} \mathsf{isofhlevel}(2)(X)$$

is not a set. Does it have an h-level?

# Sets and propositions

It is often useful for types representing "properties" to be propositions (as we'll see later).

Properties involving equality are usually propositions when the types involved are *sets*, but in general care is needed: given  $f: X \rightarrow Y$ ,

isInjective(f) := 
$$\prod_{x,x':X} f(x) \rightsquigarrow f(x') \rightarrow x \rightsquigarrow x'$$

is not a proposition in general, but it is if *X* is a set.

### Exercise

Define  $\mathsf{isInjective}(f)$  in a such a way that it is a proposition for X and Y of any level.

## Isomorphism vs. equivalence

Given  $f: A \to B$ ,

$$\mathsf{isiso}(f) \ :\equiv \ \sum_{g:B \to A} (g \circ f \leadsto \mathbf{1}_A) \times (f \circ g \leadsto \mathbf{1}_B)$$

is **not** a proposition in general, but it is if *A* and *B* are sets.

## Warning

Stating the univalence axiom with isomorphisms instead of equivalences yields an inconsistency.

When A and B are sets, then  $isiso(f) \simeq isequiv(f)$ .

3 Subtypes, relations, set-level quotient

Algebraic structures

## Predicates on types

A **subtype** A on a type X is a map

$$A: X \to \mathsf{Prop}$$

### Exercise

Show that the type of subtypes of *X* is a set.

The **carrier** of a subtype *A* is the type of elements satisfying *A*:

$$carrier(A) := \sum_{x \in X} A(x)$$

# Relations on a type

A **binary relation** *R* on a type *X* is a map

$$R: X \to X \to \mathsf{Prop}$$

#### Exercise

Show that the type of binary relations on X is a set.

Properties of such relations are defined as usual, e.g.,

$$reflexive(R) := \prod_{x \in X} R(x)(x)$$

### Exercise

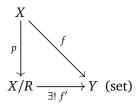

Formulate the properties of being symmetric, transitive, an equivalence relation.

## Set-level quotient

Given type *X* and an equivalence relation *R* on *X*, the **quotient** 

$$X \xrightarrow{p} X/R$$

is defined as the unique pair (X/R, p) such that any compatible map f **into a set** Y factors via p:

I.e., the map given by precomposition with p is an equivalence

$$\sum_{f:X\to Y} \mathsf{iscompatible}(f) \simeq X/R \to Y$$

# The quotient set

To define the quotient X/R of a set by an equivalence relation, we proceed as usual in set theory:

• First we define for a subtype  $A: X \to \mathsf{Prop}$ 

iseqclass(A) := ||carrier(A)||  

$$\times \prod_{x,y:A} Rxy \to Ax \to Ay$$

$$\times \prod_{x,y:A} Ax \to Ay \to Rxy$$

Then we define

$$X/R :\equiv \sum_{A:X\to \mathsf{Prop}} \mathsf{iseqclass}(A)$$

#### Exercise

Show that X/R is a set. Show that it has the desired universal property of a quotient.

## Reminder: paths between pairs

Given  $B: A \to \mathsf{Type}$  and a, a': A and b: B(a) and b': B(a'),

$$(a,b) \leadsto (a',b') \simeq \sum_{p:a \leadsto a'} \operatorname{transport}^{B}(p,b) \leadsto b'$$

If B(x) is a proposition for any x : A, then this can be simplified to

$$(a,b) \rightsquigarrow (a',b') \simeq a \rightsquigarrow a'$$

### Exercise

Why?

### Monoids

Traditionally (in set theory), a monoid is a triple  $(M, \mu, e)$  of

- a set M
- a multiplication  $\mu: M \times M \to M$
- a unit  $e \in M$

subject to the usual axioms: associativity, and left and right neutrality.

# Monoids in type theory

In type theory, a monoid is a tuple  $(M, \mu, e, \alpha, \lambda, \rho)$  where

- 1. *M* : Set
- 2.  $\mu: M \times M \to M$  (multiplication)
- 3. e:M (neutral element)
- 4.  $\alpha: \Pi_{(a,b,c:M)}\mu(\mu(a,b),c) \rightsquigarrow \mu(a,\mu(b,c))$  (associativity)
- 5.  $\lambda : \Pi_{(a:M)}\mu(e,a) \rightsquigarrow a$  (left neutrality)
- 6.  $\rho: \Pi_{(a:M)}\mu(a,e) \rightsquigarrow a$  (right neutrality)

# Monoids in type theory

In type theory, a monoid is a tuple  $(M, \mu, e, \alpha, \lambda, \rho)$  where

- 1. *M* : Set
- 2.  $\mu: M \times M \to M$  (multiplication)
- 3. e:M (neutral element)

4. 
$$\alpha: \Pi_{(a,b,c:M)}\mu(\mu(a,b),c) \leadsto \mu(a,\mu(b,c))$$
 (associativity)

5. 
$$\lambda : \Pi_{(a:M)}\mu(e,a) \rightsquigarrow a$$
 (left neutrality)

6. 
$$\rho: \Pi_{(a;M)}\mu(a,e) \rightsquigarrow a$$
 (right neutrality)

Why M: Set?

# Monoids in type theory

In type theory, a monoid is a tuple  $(M, \mu, e, \alpha, \lambda, \rho)$  where

- 1. *M* : Set
- 2.  $\mu: M \times M \to M$  (multiplication)
- 3. *e* : *M* (neutral element)

4. 
$$\alpha: \Pi_{(a,b,c:M)}\mu(\mu(a,b),c) \rightsquigarrow \mu(a,\mu(b,c))$$
 (associativity)

5. 
$$\lambda: \Pi_{(a:M)}\mu(e,a) \rightsquigarrow a$$
 (left neutrality)

6. 
$$\rho: \Pi_{(a:M)}\mu(a,e) \rightsquigarrow a$$
 (right neutrality)

Why M: Set?

Abstractly, a monoid is a (dependent) pair (data, proof) where

- data is a triple  $(M, \mu, e)$  as above
- *proof* is a triple  $(\alpha, \lambda, \rho)$  saying that (data) satisfy the usual axioms.

# The type of monoids

- We want to regard two monoids (data, proof) and (data', proof') as being the same if data is the same as data'.
- This is ensured if the type encoding the monoid axioms is a proposition.
- This is in turn guaranteed as long as the underlying type *M* is required to be a **set**.

$$\mathsf{Monoid} \ :\equiv \ \sum_{(M:\mathsf{Set})\,(\mu,e):\mathsf{MonoidStr}(M)} \mathsf{MonoidAxioms}(M,(\mu,e))$$

with

$$isProp(MonoidAxioms(M, (\mu, e)))$$

## Monoid isomorphisms

Given monoids  $\mathbf{M} \equiv (M, \mu, e, \alpha, \lambda, \rho)$  and  $\mathbf{M}' \equiv (M', \mu', e', \alpha', \lambda', \rho')$ , a **monoid isomorphism** is a bijection  $f : M \cong M'$  preserving multiplication and neutral element.

$$\begin{split} \mathbf{M} &\leadsto \mathbf{M}' &\simeq (M,\mu,e) \leadsto (M',\mu',e') \\ &\simeq \sum_{p:M \leadsto M'} (\mathsf{transport}^{Y \mapsto (Y \times Y \to Y)}(p,\mu) \leadsto \mu') \\ &\qquad \times (\mathsf{transport}^{Y \mapsto Y}(p,e) \leadsto e') \\ &\simeq \sum_{f:M \cong M'} \left( f \circ m \circ (f^{-1} \times f^{-1}) \leadsto m' \right) \\ &\qquad \times (f \circ e \leadsto e') \\ &\simeq \mathbf{M} \cong \mathbf{M}' \end{split}$$

# Paths are isomorphisms for groups

$$\mathbf{G} \leadsto \mathbf{G}' \simeq (G,S) \leadsto (G',S')$$

$$\simeq \sum_{p:G \leadsto G'} \operatorname{transport}^{\operatorname{GrpStructure}}(p,S) \leadsto S'$$

$$\simeq \sum_{p:G \leadsto G'} (\operatorname{transport}^{Y \mapsto (Y \times Y \to Y)}(p,m) \leadsto m')$$

$$\times (\operatorname{transport}^{Y \mapsto (Y \to Y)}(p,i) \leadsto i')$$

$$\times (\operatorname{transport}^{Y \mapsto Y}(p,e) \leadsto e')$$

$$\simeq \sum_{f:G \simeq G'} (f \circ m \circ (f^{-1} \times f^{-1}) \leadsto m')$$

$$\times (f \circ i \circ f^{-1} \leadsto i')$$

$$\times (f(e) \leadsto e')$$

$$\simeq (\mathbf{G} \cong \mathbf{G}')$$

## Transport along group isomorphism

We now have two ingredients:

- 1.  $(\mathbf{G} \leadsto \mathbf{G}') \simeq (\mathbf{G} \cong \mathbf{G}')$
- 2. transport<sup>T</sup>:  $(\mathbf{G} \leadsto \mathbf{G}') \to T(\mathbf{G}) \to T(\mathbf{G}')$  for any structure T on the type of groups

Composing these, we get

$$\mathsf{transport}^T: (\mathbf{G} \cong \mathbf{G}') \to T(\mathbf{G}) \to T(\mathbf{G}')$$

In other words, any property or structure on groups that can be expressed in univalent type theory can be transported along isomorphism of groups.

## Structure Identity Principle

The Structure Identity Principle (Coquand, Aczel) says
Isomorphic mathematical structures are structurally identical; i.e. have the same structural properties.

The Structure Identity Principle holds in Univalent Foundations for many algebraic structures: isomorphic such structures have **all** the same (definable) properties.
